

Mathematics into School - Project Report

Tom Mann

April 23, 2025

Abstract

This report details a project delivered in partnership with Our Lady and st Thomas Catholic primary school with the aim of increasing girls confidence in maths and decreasing cases of maths anxiety. Over a series of six sessions a group of girls were introduced to a variety of mathematical content. The pedagogical insight behind the mathematical content, design and delivery of these sessions will be examined. Finally the report will evaluate the success of the project in regards to confidence, anxiety, along with the legacy to the students.

1 Introduction

1.1 Context

This project was conducted in partnership with Our lady and st Thomas school (OLST), a co-educational Catholic primary school consisting of around 120 students. The school has strong academic results, the percentage of students achieving expected or higher standard in reading, writing and maths is above the national and local average [1]. However it has been observed that some girl in the year six class lack confidence in maths lessons and interact less than hoped. Boy are often likely to take up more space in a classroom and require more movement than girls, this is not out of rudeness it is just a difference in environmental learning styles [2]. Along side this it has been found that boys tend to initiate more exchanges whereas girls prefer to be respondent, to be called on by a teacher [3]. While some of this contrast in preference may be explained by biological difference, it may be that there is a confounding variable such as self-confidence.

1.2 Aims

There were two main aims for the project, although they may appear similar and overlap in some aspects they are distinct.

Aim 1 – Increasing self-confidence in girls in maths

Confidence within any subject is the belief that you can rely on you own abilities. It appears that there are two ways to increase self-confidence; either improve students abilities or improve the belief in their own abilities. Nationally and in the North East the percentage of girls and boys achieving the expected standard in their maths SATs has been within 2 percentage points of each other since 2018/19 [4]. This suggests that while increasing girls abilities in maths may increase their confidence this may not be the main cause of a lack of self-confidence. One study found two differences in the mindset of girls and boys [5]. Firstly "girls tend to attribute failure in mathematics to a lack of ability whereas boys attribute failure to a lack of effort", and second girls are more likely to attribute success to external factors, such as an easy exam. This leads to a dichotomy where many girls take responsibility for their failures but do not take credit for their successes. So it was decided the best way to tackle self-confidence was in the mindset of girls.

Aim 2 – Decreasing maths anxiety in girls

Maths anxiety is in the broadest sense a feeling of worry or nervousness combined with physiological reactivity to current or future situations involving maths [6]. While this is related to low self-confidence in maths, it is possible to have one without the other. Similarly to self-confidence, girls seem to be disproportionately affected. The National Numeracy survey found that women were twice as likely to experience maths anxiety as men [7], however it is important to note general anxiety is also higher amongst girls. It has been found that there is a negative relationship between maths anxiety and maths performance, that is higher maths anxiety is linked to poor performance [8]. There are various studies around the cause and effect relationship between maths anxiety and maths performance, it is not widely agreed upon if one causes the other or many believe that the relationship may be cyclic [8]. This again means that one cannot simply treat maths anxiety by improving maths performance. When dealing with maths anxiety it is important to treat both the cause and the symptoms, treating the symptoms of anxiety is more

aligned with behavioural therapy, this report will focus on treating the cause of maths anxiety.

1.3 Introduction to Students

Due to the nature of the aims, this project is very individual. It was decided to spend some time to learn the experiences of the students who would be taking part in the sessions. One session was spent talking to the girls in the class to find out more about what the prevalence of maths anxiety was amongst the girls and what are the causes of the maths anxiety. All of the students in the session agreed with each other that they had been worried in maths lessons before. It was clear that all of the students had experienced maths anxiety before so it was not appropriate or necessary to find out more about individual experiences of anxiety, it was more important to find out the causes of the the anxiety.

The girls identified three main causes of maths anxiety: a fear of failure, judgement, and being left behind. One student added that maths feels frustrating because when they don't understand something, they feel stuck and unable to progress. It was with these insights in mind that the sessions were designed.

2 Activities

2.1 Structure

The year 6 class this project was taking part with had 8 girls in it, it was decided to include all of the girls from the class in the sessions. This may have reduced the amount of time that could be spent with each student, however in such a small class excluding only a few students would be unfair.

It has been found that maths anxiety is often linked to teaching style, in particular in a traditional classroom setting the teacher takes an authoritative role [9]. To mediate this the sessions would be delivered around a group table with everyone sitting to reduce my presence as a directive role.

2.2 Session 2: Möbius strips

This session was designed with two strategies for dealing with maths anxiety in mind. The first stems again from the link between delivery methods and maths anxiety, in particular traditional delivery methods focus on the outcome of a lesson, whether that be students gaining specific knowledge or being able to answer certain questions correctly. The remedy to this is a more constructivist approach to teaching focusing on the process rather than the product [9]. The second strategy is focused on Expectancy-Value Theory, "ACER's Mathematics anxiety and Engagement Strategy" outlines four different types of value that are important motivation, we shall focus on intrinsic value in this session and utility value later on [10]. Intrinsic value comes simply from finding value in maths because you find it interesting or enjoyable.

To align with the goal of focusing on the process of learning, the first session was created with no learning outcome in mind, that is there is no expectations for the students to learn or recreate anything from the session. The intrinsic value of the session comes from exploring a shape the students will most certainly never have seen before, with properties they will never have seen before.

Figure 1: Möbius strip

A Möbius strip is created by taking a strip of paper, giving it a half-twist, and then joining the ends together. This creates a one sided, one edged surface. The session consisted of the students working in pairs to: make, draw on and cut the Möbius strips. These aspects of the session align with two constructivist methods, group work and manipulation of materials as a primary source of information.

There was demonstration in front of the children of how to create a Möbius strip, they then worked in pairs, sometimes with external help to construct their own Möbius strip. The children were then told to draw length ways along the Möbius strip until they get back to the start. This appears to end up with a line on "both" sides of the shape even though the students only drew one line. Through this task alone the students didn't realise the surface only had one side, so they were asked a slightly incorrect question of "You only drew on one side but there is a line on both sides, how is this possible?". Through constructing a destructing more Möbius loops the students explored how a surface can have only one face.

The next task involved the students cutting down the line they had drawn. Unexpectedly the surface does not end up in two pieces, but stays as one loop with more twists in it. This property was impossible for the students to miss when they completed this task. This property was more difficult to explain simply by building Möbius strips, so in the session a prop was created by writing left and right at the end of the end of the strip so that left would align with left and right with right when the end were joined without a twist. The students could then observe that when we add a half-twist to make a Möbius strip that left joins with right and vice versa. This showed that when they cut the strips there is no left and right side for them to split into. Note, here left and right do not have any meaning and are only to show that the sides do not join as expected.

2.3 Session 3/4: Statistics

While the previous activity focused on intrinsic value, this one — delivered over two lunchtime sessions — was designed, among other things, to incorporate a utility value intervention. This is finding value in maths because you consider it useful for future or present goals [10]. The second goal of this session was to get students talking about maths with their parents. It has been shown that parental involvement can affect children's mathematics performance by reducing mathematics anxiety [11]. However other studies have found that children of maths anxious parents learn less maths over the school year and have more maths anxiety by the end of the year only if the parents report helping frequently with maths homework [12]. As a result of this, involvement of parents was aimed to be based around discussion rather than maths questions.

The topic of statistics was chosen as it is on the national curriculum, so the students should have seen it before, and it offers many areas of application for the students to explore. This activity was split over two sessions so the students could collect data in between the sessions to use in the second session. The majority of the first session was spent discussing what statistics is and why it is useful. The students were then presented with a sheet for them to use to collect data, specifically hair colour, eye colour and age. The aim was for students to take these sheets home and to collect data by speaking to their family. The sheet also contained a brief task for the students to research or speak to their parents about a use for statistics, incentivised by a reward of points from a system used in the school.

The second session focused on the students analysing the data they had collected, this

was to be done through the students drawing bar charts and working out averages. A sheet of fake data was created for students who forgot their sheets. The session started with the students using examples of bar charts to see that they are easier to read off of than a table of data. The students then constructed their own bar charts for hair and eye colour on a sheet designed to offer guidance. This task was completed quicker than anticipated, so the session was adapted to teach the children about the median. The children lined themselves up in age order, and then the middle student was taken as example of a median of their ages. This again links to a constructivist approach to teaching deviating from a traditional delivery method, with the students themselves being a primary material to learn from.

Evaluation

This task failed to meet the desired aims in two main ways: the mode of delivery and promoting discussion around maths. Due to this session being focused on utility value, this meant trying to fit a larger amount of content into the sessions, and falling back to a more traditional delivery style. Specifically there was one authoritative role in the classroom and although sessions were discussion based the students were still completing worksheets. One student exclaimed "Ughh, not a worksheet" at the beginning of the first session. This shows how much a traditional delivery style is linked to maths anxiety or at least a lack of enjoyment.

A large aim of this session was promoting discussion around maths with parents and family members through the data collection and researching statistics. As the data the students had to collect was so trivial (hair colour, eye colour and age), the students simply recalled the information and wrote it down on the sheet without speaking to anyone. Although some students showed interest in finding uses of statistics at the end of the first session, none of them completed any research on their own. The vast majority of students either lost the data they collected or forgot to bring it in, this means any motivation provided by the students working on their own data was lost.

The rest of the sessions were designed to be self contained and to avoid overlapping with traditional delivery methods where possible.

2.4 Session 5: Coordinate Grid

With the limitations of the previous sessions in mind, it was important that the mode of delivery for this activity was different. All previous sessions had taken place with the students sitting around a group table, so this activity was designed to allow more movement in the children. Up until this point the students hadn't worked collaboratively, as much as they hadn't worked towards one goal or shared this answer. One study suggests that "incorporating cooperative groups in problem-solving situations, where pupils, given a variety of problems; work together and share their solutions" helps to reduce maths anxiety [13]. When students are working together towards a common goal through different problems, they may not worry about competing with their classmates as much as if they were all doing the same questions.

The content of this session would be a mixture of something new in the form of the coordinate grid, combined with revision of content the students had covered in the previous weeks. This would hopefully make the students feel more comfortable as they will feel more confident when they see material they have already covered. To begin with the students were introduced to the coordinate grid, and told how to read off a point from the grid. Before the session began a coordinate grid, where each point was a piece of paper

was laid out on the floor. On the back of some of the pieces of paper were questions on topics the students had recently covered. The answers to these questions would lead the students to a new point and a new set of questions and so on, revealing where a prize was hidden along the way. It was required that each student solve at least one question to get the prize at the end.

Evaluation

The form of this session worked well at reducing anxiety in students. Every time a new clue was discovered, students were asked who would like to complete it, all of the students who hadn't completed a clue yet volunteered. This is not something you would see happen during a normal lesson, with students stating that they are worried about other classmates judging them. As the students were working towards a common goal they do not have to worry about other students judging them, as it benefits the other students if everyone is supported and does well.

2.5 Session 6: 1-2 Nim

While the previous activities had used some constructivist approaches to teaching, for this session it would be the main focus. One study of students aged around 12 found that the difference in maths anxiety of those taught with constructivist approach against a control group was significant at a level of 0.01 [14]. Moreover when looking only at girls, the difference was more significant (i.e. a higher t-value) than when looking at only boys or a mixed group. However this study fails to mention the specifics of the constructivist approach that was adopted.

The approach used in the following activity is "Discovery Learning" first outlined by Jerome Bruner [15]. Discovery learning takes place in a problem solving environment where students draw on previous knowledge and manipulate objects to discover new facts and relationships [16]. This session was based around the game "1-2 Nim" taken from the math for love website [17], the aim was for students to discover their own strategies for the game. The simplest version of this game involves two players and eight counters, students take turns taking either one or two counters and the student to take the last counter wins.

This game was demonstrated by playing against a student until it was clear everyone understood the game. The students were then invited to play against each other, this allows them to explore the game without any agenda. The students were then brought back to use a powerful problem solving technique to start discovering strategies, they were asked how we could make the game simpler. With some guidance students then discussed the trivial strategy for playing with one or two counters and then the slightly more difficult case of three counters (here you wish for your opponent to take first). For the rest of the session the students left to play against each other to discover the best strategy for four to eight counters. While constructivism and discovery learning does not mean you should never tell students anything directly, in this activity this was the case. Students conjectured strategies which were tested by playing against other students or myself. The students organised this information by creating a table of their strategy for each number of counters. At the end of the session the students could use their tables they had created to play against me, this is a strong example of student ownership. The students built a tool, they use it, they own it.

3 Evaluation

3.1 Consideration of Original Aims

Due to the nature of the aims of this project it was difficult to elicit any quantitative evidence for the original aims. It was not deemed appropriate to ask students about their self reported levels of maths anxiety as this could simply lead to students feeling more anxious or becoming more aware of maths anxiety. The aims of the project will be evaluated through observation and qualitative feedback.

Aim 1 – Increasing self-confidence in girls in maths

As the sessions progressed it was observed that the girls became willing to contribute. In the first session the students tentatively raised their hands when they were asked questions and as sessions went on students were so eager to contribute they often spoke over each other. While it is clear the students became more confident throughout the sessions it is difficult to distinguish the cause. It is likely the a significant proportion of the increase in confidence came about simply through the students acclimatising to the environment of the sessions.

One noticeable incident occurred during the first session of the statistics activity. When the students were asked if they knew what data was in relation to statistics none of them volunteered an answer initially, after a few seconds one student raised her hand and said "is it information?". This student was unsure of themselves initially but still gave an answer. This is unlikely to have occurred in a regular classroom setting, it is most likely the small group size and possibly the more informal environment that made the student feel more confident. This could also be looked at as evidence of decreased maths anxiety, the student was unsure of themselves but willing to contribute as they are less worried about the consequences of an "incorrect" answer.

Aim 2 – Decreasing maths anxiety in girls

It is easier to evaluate the limitations of this project in regards to this aim than it is it's successes. Throughout the project there were some examples of students exhibiting behaviour suggesting they may be feeling anxious. In particular the coordinate grid session which involved students working out problems on their own sometimes required children to sit down and spend a minute or two solving the more challenging questions. When one student was sat down solving a question, other students came over to look as they were eager to get through the session. This made the student who was solving the problems nervous, and she said that she didn't like people watching her. This was likely due to a fear of judgement that she would get the questions wrong or she was taking to long to solve the questions. Although this session was designed so the students would be working together, the format meant that one student would be working at a time, placing a lot of pressure on that student.

The most notable proxy for the success of the project in regards to this aim was the enjoyment and the enthusiasm the children exhibited for the sessions. All of the students were eager to turn up to the sessions later into the project, and seemed disappointed that the sessions would be ending. While this is clearly a very loose metric of decreased anxiety, increased enjoyment likely means that the methodology behind the design of the sessions was effective. That is, increased enjoyment is likely caused by the same design choices to decrease anxiety, such as approaching a more constructivist approach and focussing more on the process of learning.

3.2 Limitations

The biggest limitation of this project was expressed by something one of the students said during the last session, which was "I enjoyed you sessions but I still don't like maths lessons". This shows that no matter how successful the sessions were at decreasing anxiety it is difficult to transfer this to maths lessons.

3.3 Legacy and Conclusion

The legacy of this project lies more with the students than any materials. During the last session a more direct approach was taken with the students in terms of talking about self-confidence. They were told how they had all clearly worked hard over the sessions and they all showed potential in maths. It is hoped that even a small positive experience with maths, such as this project, will stay with some of the students and inspire them in the future.

Overall this project has highlighted how effective lesson planning can alleviate anxiety, but it has also shown how a holistic approach is required to cover all facets of maths anxiety.
